Abstract:

In a signal processing unit of a hearing device, the signal
5 processing unit consisting of a signal analyzing unit and a
signal identification unit, the momentary acoustic surround
situation is identified. Based on this identified surround
situation, the parameter set belonging to the identified
surround situation is automatically adjusted in a
10 transmission unit in which a number of parameter sets are
saved which are assigned to different acoustic surround
situation. The hearing device user can adjust his
individual hearing desire for each acoustic surround
situation according to the automatic adjusted parameter set
15 with the aid of an input unit. Thereby, the parameter of
this parameter set are adjusted at the same time and
commonly in one of two opposing directions, e.g. in the
sense of "better hearing" or in the sense of "more pleasant
understanding".
